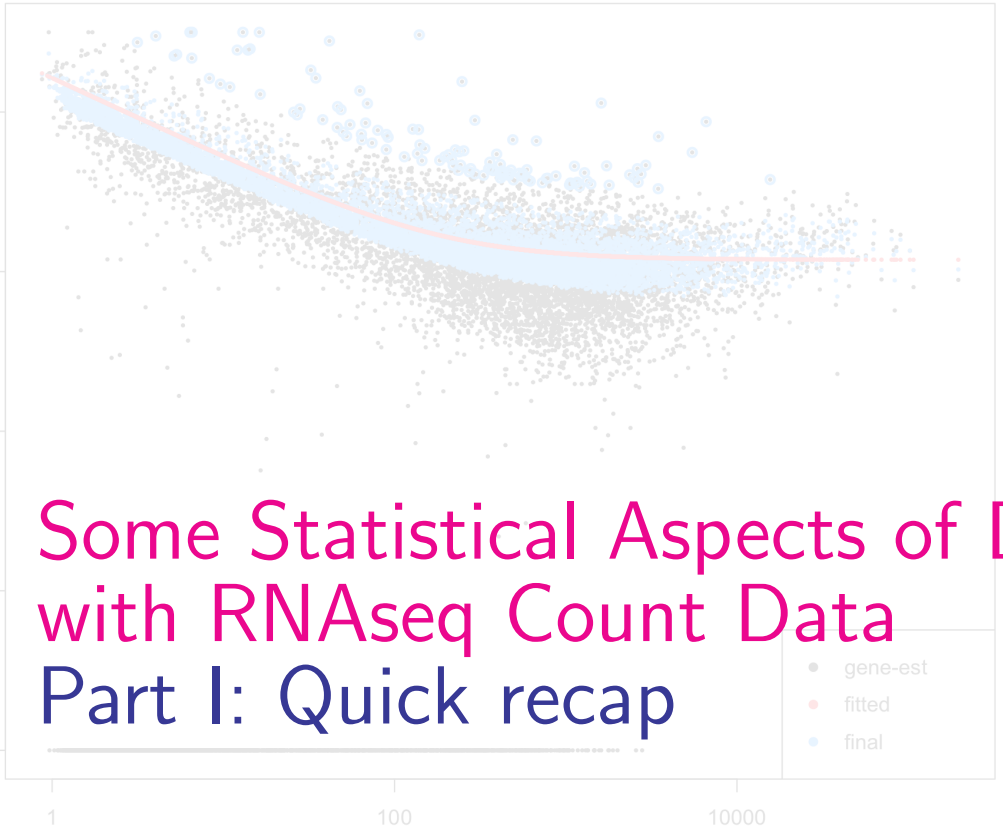
Outline

- Part I: Quick recap
  - Tests: Null and alternative hypotheses, Type I and type II errors, Power
  - Experimental design & Sample size calculation.
- Part II: Modelling
  - X design matrix,
  - Linear regression,
  - Negative binomial regression for counts.
- Part III: Multiplicity correction
  - Familywise error rate (FWER)
  - False discovery rate (FDR)



Some Statistical Aspects of DE Analysis with RNAseq Count Data

Part I: Quick recap

dominique-laurent.couturier@cruk.cam.ac.uk [Bioinformatics core]

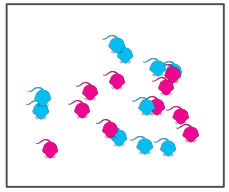
Grand Picture of Statistics

Statistical Hypotheses

H0: $\mu_I = \mu_U$

H1: $\mu_I \neq \mu_U$

Sample/Sequencing/alignment



Idea:

EGF is differentially expressed (DE) in infected (I) and uninfected (U) mice

Data: RNASeq counts

$(y_{I,1}; y_{I,2}; ...; y_{I,n_I})$

$(y_{U,1}; y_{U,2}; ...; y_{U,n_U})$

Point estimation

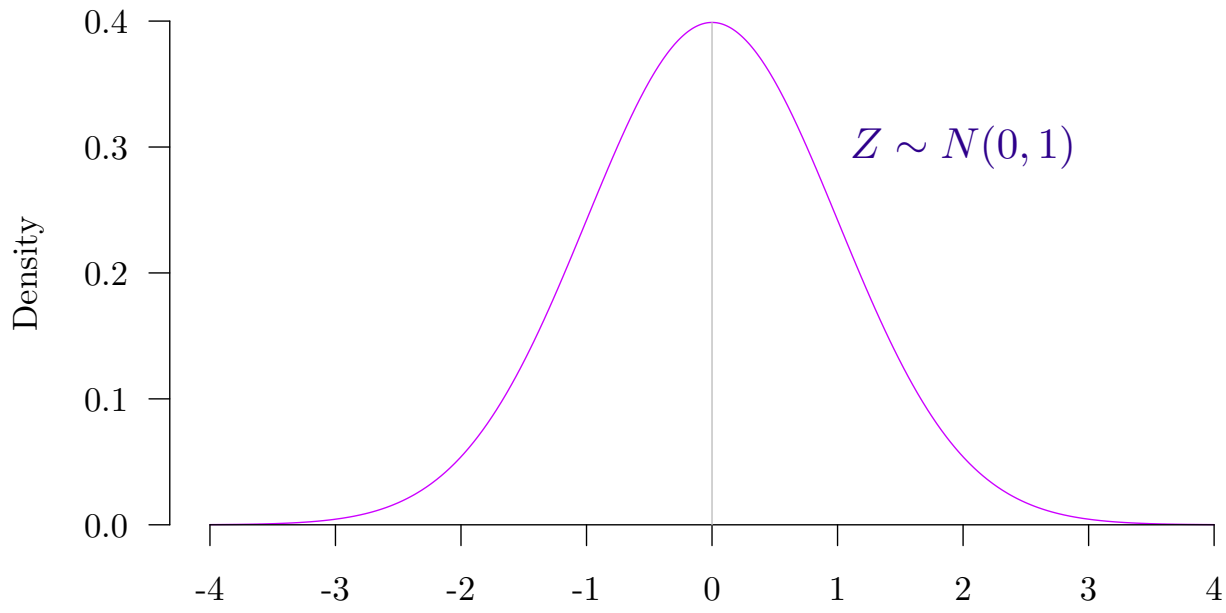
$\widehat{\mu}_I - \widehat{\mu}_U$

Inference

$$T_{obs} = \frac{\widehat{\mu}_I - \widehat{\mu}_U}{s_p \sqrt{\frac{1}{n_I} + \frac{1}{n_U}}} \sim St_{n_I + n_U - 2}$$

Statistical tests

Assess how likely the observed test statistics is
compared to the test statistics distribution under H0:



P-value for a two-sided test:

p-value $= 2 \min \left[P(Z \leq Z_{obs} | \text{H0}), P(Z \geq Z_{obs} | \text{H0}) \right]$

i.e. the probability of getting a test statistic as extreme or more extreme than the calculated test statistic if H0 is true

Statistical tests

4 possible outcomes

Conclude:

- if p-value $> \alpha$ $\rightarrow$ do not reject H0.
- if p-value $< \alpha$ $\rightarrow$ reject H0 in favour of H1.

		Test Outcome	
		H0 not rejected	H1 accepted
Unknown Truth	H0 true	$1-\alpha$ [TN]	α [FP]
	H1 true	β [FN]	$1-\beta$ [TP]

where

- α is the type I error, the probability of rejecting H0 when H0 is correct,
- β is the type II error, the probability of not rejecting H0 when H1 is correct.

Warnings

- 'absence of evidence is not evidence of absence',
- design may help minimising FP and FN (ie, maximising TN and TP).

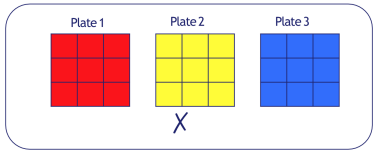
Experimental design 1: Minimising biases

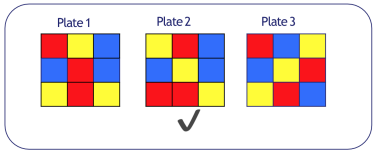
3 fundamental aspects of sounds experiments (Fisher 1935)

- **Replication**
  Try to capture all sources of variability
  (Biological versus technical variability)

- **Blocking**
  Try to remove technical biases/confounding
  (Lane and batch effects)

- **Randomisation**
  Try to remove confounding due to other factors





Experimental design 2: boosting power

Power- / Effect size- / Sample size- calculations

4 ingredients:

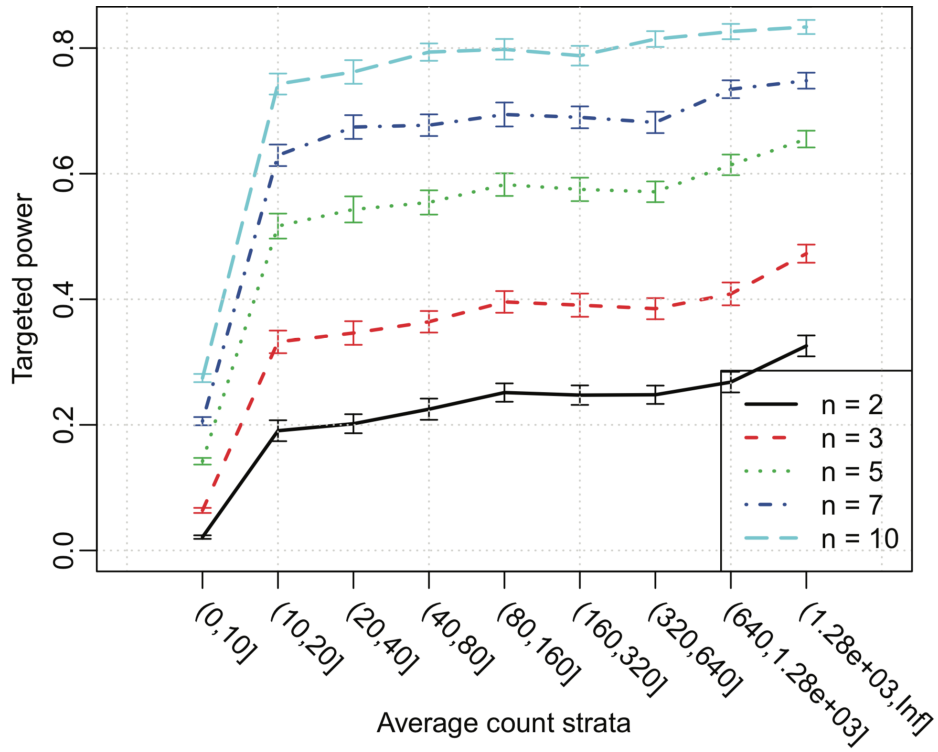
- $1 - \beta$, the power,
- δ, the effect size: function of μ_L and μ_B (log fold change, standardised difference),
- n, the sample size (number of biological replicates),
- α, the type I error.
  - ϕ, nuisance parameters (variability, sequencing depth, multiplicity correction)

'Give me 3 of them, I will deduce the fourth':

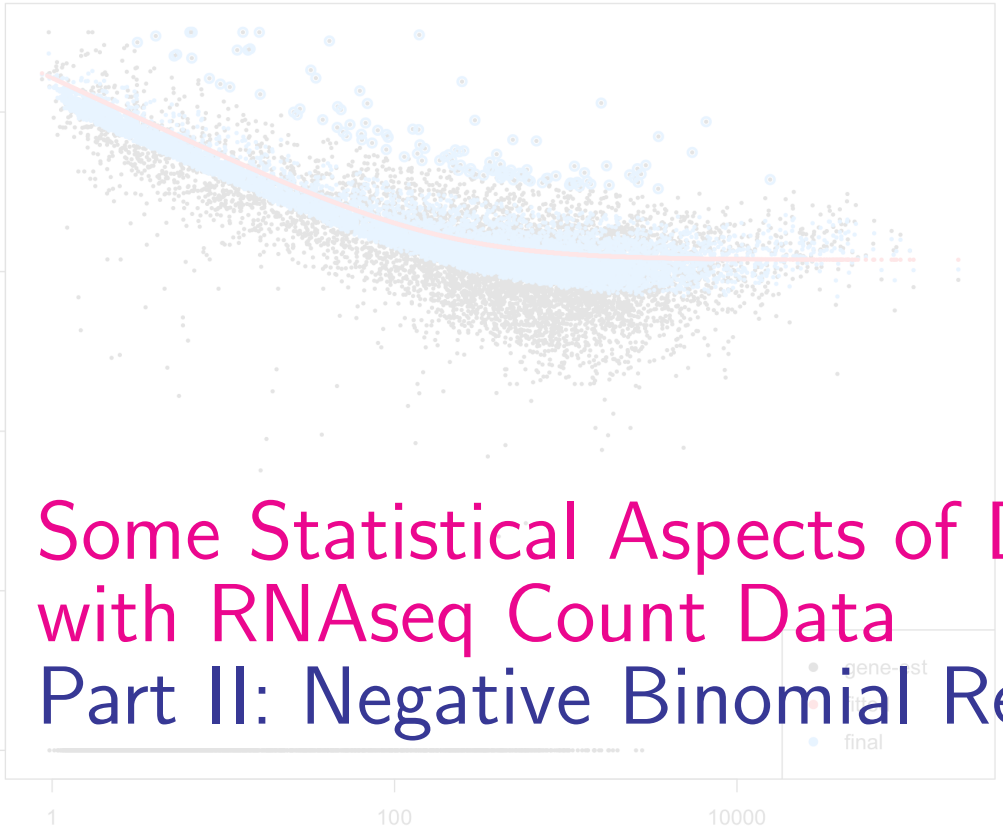
- Power calculation: Aim is to define the probability $(1 - \beta)$ to detect an effect size of interest (δ) at the α level with a sample size of n biological replicates.
- Sample size calculation: Aim is to define the sample size (n) allowing to detect an effect size of interest (δ) at the α level with a given probability $(1 - \beta)$.

Experimental design 2: boosting power

Power- calculations in DE analyses



(Wu, Wang and Wu (2015))



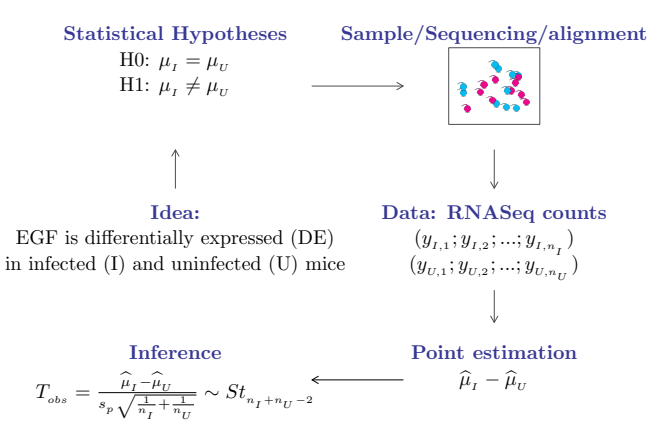
Some Statistical Aspects of DE Analysis with RNAseq Count Data

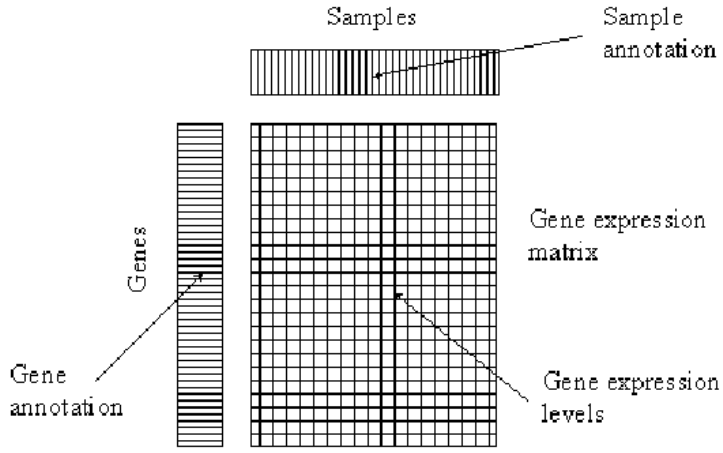
Part II: Negative Binomial Regression

dominique-laurent.couturier@cruk.cam.ac.uk [Bioinformatics core]

(Source: O. Rueda, MRC-BSU)

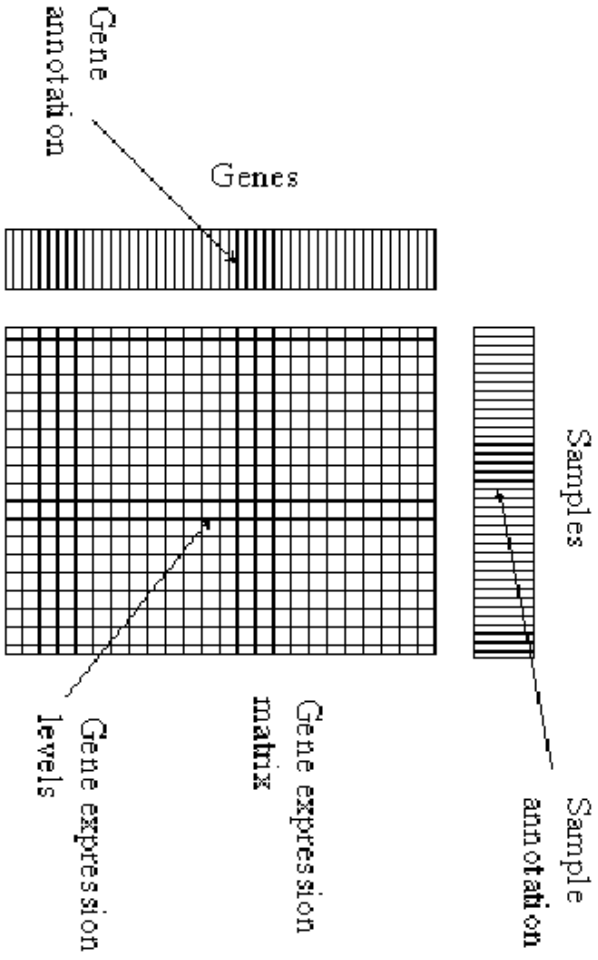
Statistical modelling





Aim: Model the count data of each gene as a function of the conditions of interest (treatment, age, sex, batch, aso.)

Statistical modelling



$$\mathbf{y} = f(\mathbf{X}) + \epsilon$$

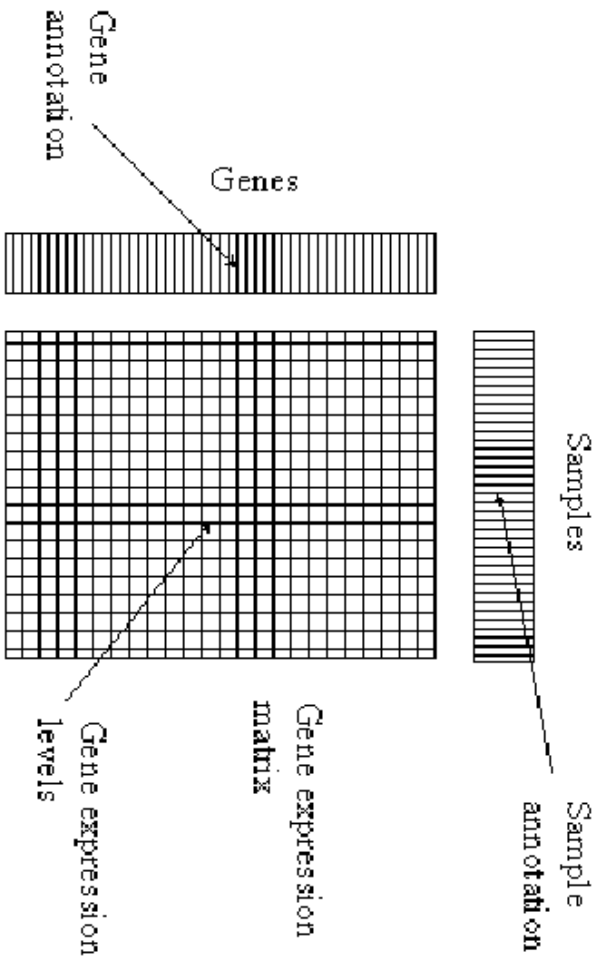
$$\mathrm{E}[\mathbf{y}] = f(\mathbf{X})$$

where

- $\mathbf{y}$ denotes the $(n \times 1)$ vector of expression intensities of a given gene,
- $\mathbf{X}$ denotes the $(n \times p)$ design/predictor matrix,
- ϵ denotes the $(n \times 1)$ stochastic error vector,
- $\mathrm{E}[\mathbf{y}]$ denotes the expectation of $\mathbf{y}$

Express the count data vector of a given gene, $\mathbf{y}$, as a function f of characteristics of the samples ($\mathbf{X}$: age, treatment, aso) plus a stochastic error vector ϵ

Statistical modelling : Linear regression



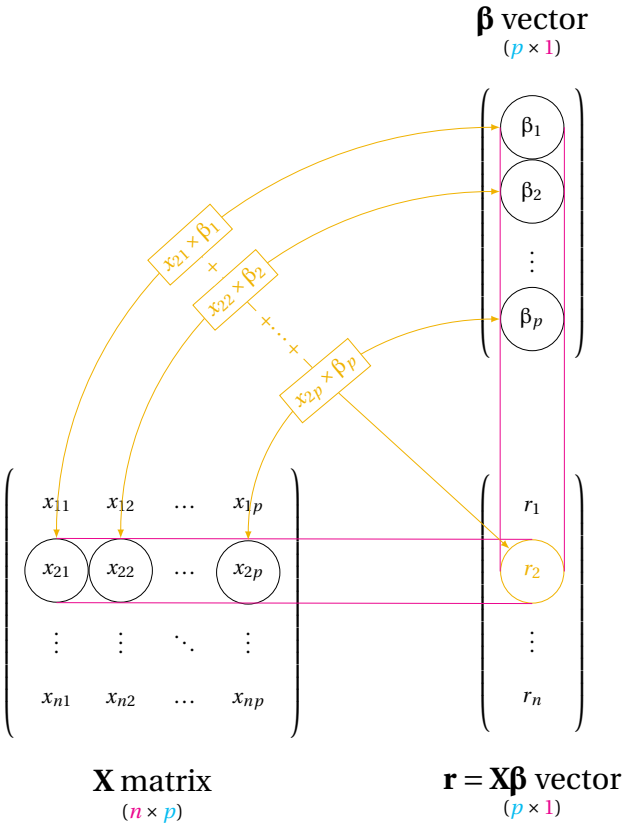
$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \epsilon$$

$$\mathrm{E}[\mathbf{y}] = \mathbf{X}\boldsymbol{\beta}$$

where

- $\mathbf{y}$ denotes the $(n \times 1)$ vector of expression intensities of a given gene,
- $\mathbf{X}$ denotes the $(n \times p)$ design/predictor matrix,
- $\boldsymbol{\beta}$ denotes the $(p \times 1)$ parameter vector,
- $\epsilon \sim N(0, \sigma^2)$ denotes the $(n \times 1)$ stochastic error vector,
- $\mathrm{E}[\mathbf{y}]$ denotes the expectation of $\mathbf{y}$

Statistical modelling : Linear regression



$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \epsilon$$

$$\mathrm{E}[\mathbf{y}] = \mathbf{X}\boldsymbol{\beta}$$

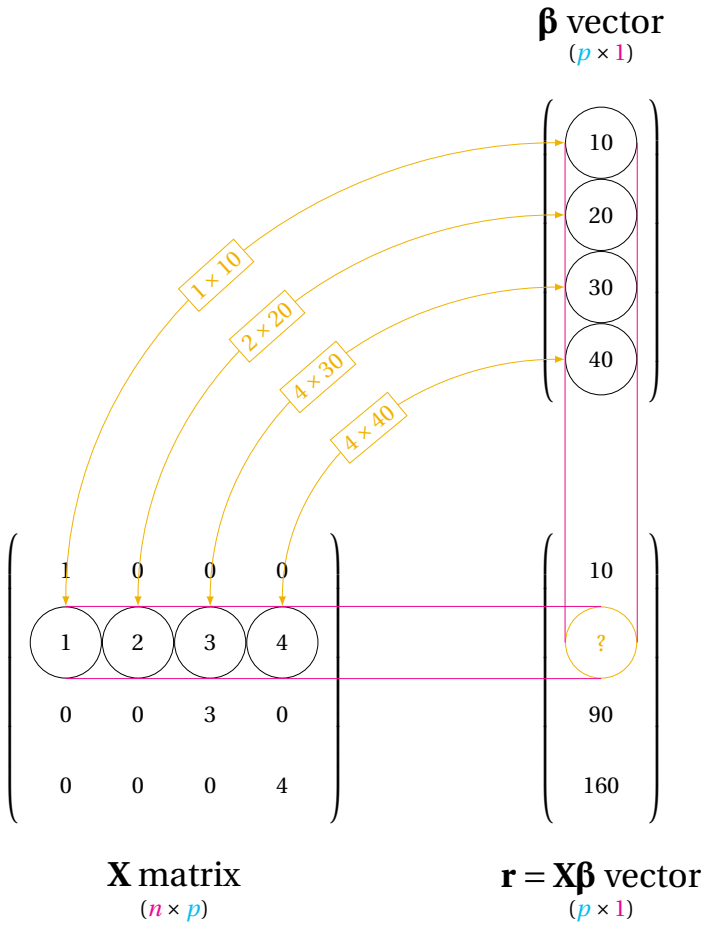
where

- $\mathbf{y}$ denotes the (n × 1) vector of expression intensities of a given gene,
- $\mathbf{X}$ denotes the (n × p) design/predictor matrix,
- $\boldsymbol{\beta}$ denotes the (p × 1) parameter vector,
- $\epsilon \sim N(0, \sigma^2)$ denotes the (n × 1) stochastic error vector,
- $\mathrm{E}[\mathbf{y}]$ denotes the expectation of $\mathbf{y}$

Matrix multiplication:
the ith element $\mathbf{r} = \mathbf{X}\boldsymbol{\beta}$ is obtained by

- multiplying **term-by-term** the entries of the ith row of $\mathbf{X}$ and each element of $\boldsymbol{\beta}$,
- and summing these products.

Statistical modelling : Linear regression



Matrix multiplication:
the ith element $\mathbf{r} = \mathbf{X}\beta$ is obtained by

- multiplying **term-by-term** the entries of the ith row of $\mathbf{X}$ and each element of β,
- and summing these products.

Statistical modelling : Strategy

- Collect the information related to each sample for the predictors of interest,
- define $\boldsymbol{\beta}$, the sets of parameters we are interested in,
- build the $\mathbf{X}$ matrix that relates the sample information with the $\boldsymbol{\beta}$
  this step is automatically done in R by specifying the regression formula in the function lm() or DEseq2()
- estimate the $\boldsymbol{\beta}$ and use statistical inference to assess significance (p-values)
  these two points are done by the function lm() or DEseq2()

Statistical modelling : $\mathbf{X}\boldsymbol{\beta}$ (For information)

- Linear regression:
  $E[\mathbf{y}] = \mathbf{X}\boldsymbol{\beta}$,
- Cox regression:
  $h(t) = h_0(t)e^{\mathbf{X}\boldsymbol{\beta}}$,
- Logistic regression:
  $\boldsymbol{\pi} = \frac{e^{\mathbf{X}\boldsymbol{\beta}}}{1+e^{\mathbf{X}\boldsymbol{\beta}}}$,
- Mean expression levels for a given gene in DESeq2:
  $E[\mathbf{y}] = 2^{\mathbf{X}\boldsymbol{\beta}}$,

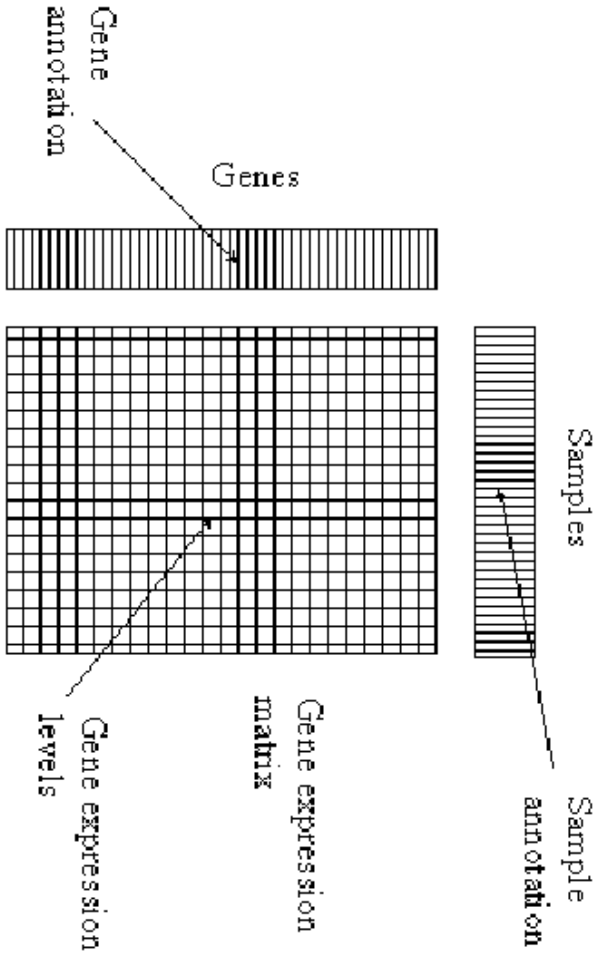
Statistical modelling : X contrast matrix

We will discuss contrast matrices for models with

- 1 factor (1 categorical predictor),
  - 2 experimental conditions (binary predictor, like sex), t-test
  - >2 experimental conditions, One-way ANOVA
- 2 factors (2 categorical predictors),
  - without interaction,
  - with interaction,

  Two-way ANOVA

Example: Toxoplasma Gondii Oocysts



#	Sample ID	Status	Time Point
1	SRR7657878	Infected	11 dpi
2	SRR7657881	Infected	11 dpi
3	SRR7657880	Infected	11 dpi
4	SRR7657874	Infected	33 dpi
5	SRR7657882	Uninfected	33 dpi
6	SRR7657872	Infected	33 dpi
7	SRR7657877	Uninfected	11 dpi
8	SRR7657876	Uninfected	11 dpi
9	SRR7657879	Uninfected	11 dpi
10	SRR7657883	Uninfected	33 dpi
11	SRR7657873	Infected	33 dpi
12	SRR7657875	Uninfected	33 dpi

2 Factors:

- Status with 2 levels (Infected/uninfected)
- Time point with 2 levels (11 dpi, 13 dpi)

https://github.com/bioinformatics-core-shared-training/Bulk_RNAseq_Course_2021/blob/main/Course_Materials/data/samplesheet_corrected.tsv

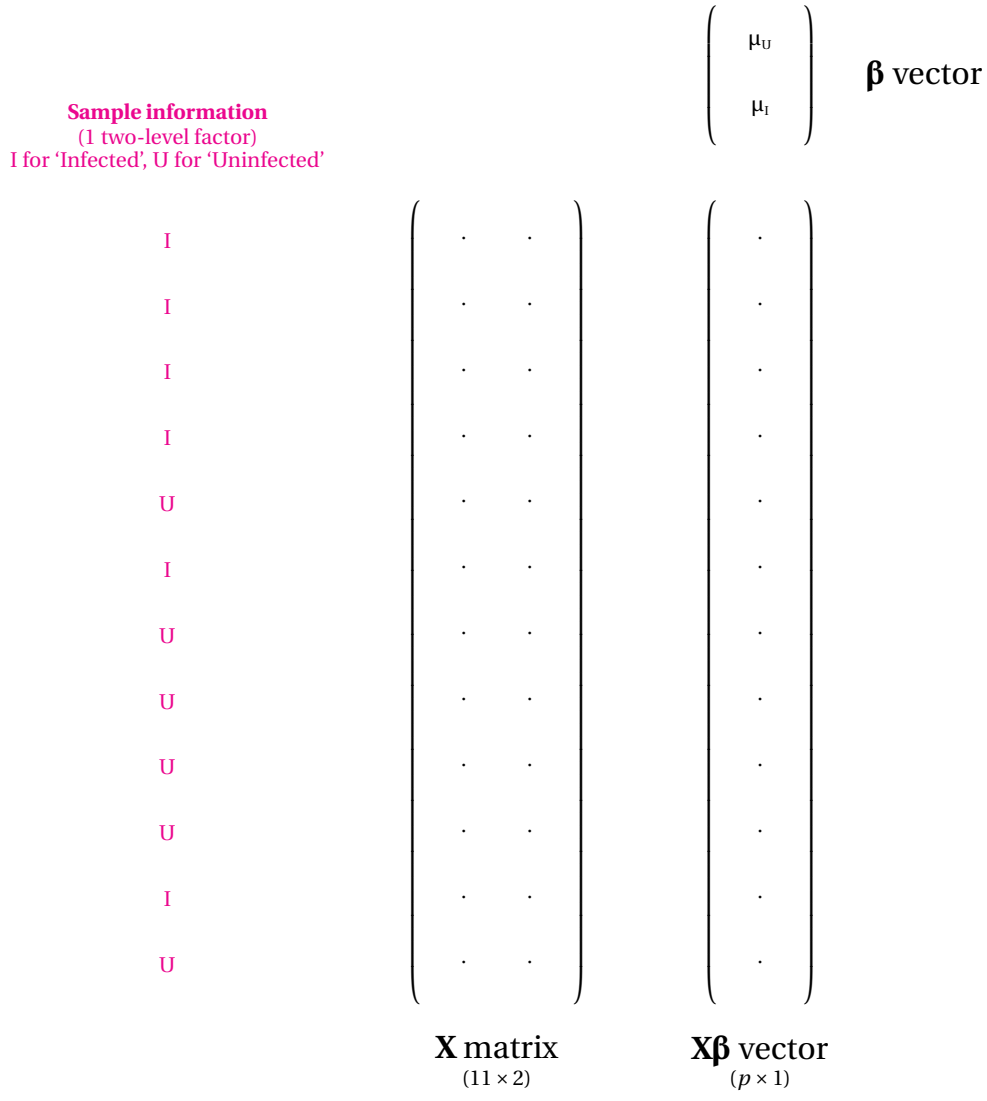
Case 1: 1 two-level factor without intercept

Modelling 1:

- Mean expression level of gene 'G' is a function of Status: Uninfected and infected.
- 2 levels = 2 parameters

Parameters: $\boldsymbol{\beta} = [\mu_U, \mu_I]^T$, where

- μ_U denoted the mean expression level for condition 'Uninfected'
- μ_I denoted the mean expression level for condition 'Infected'



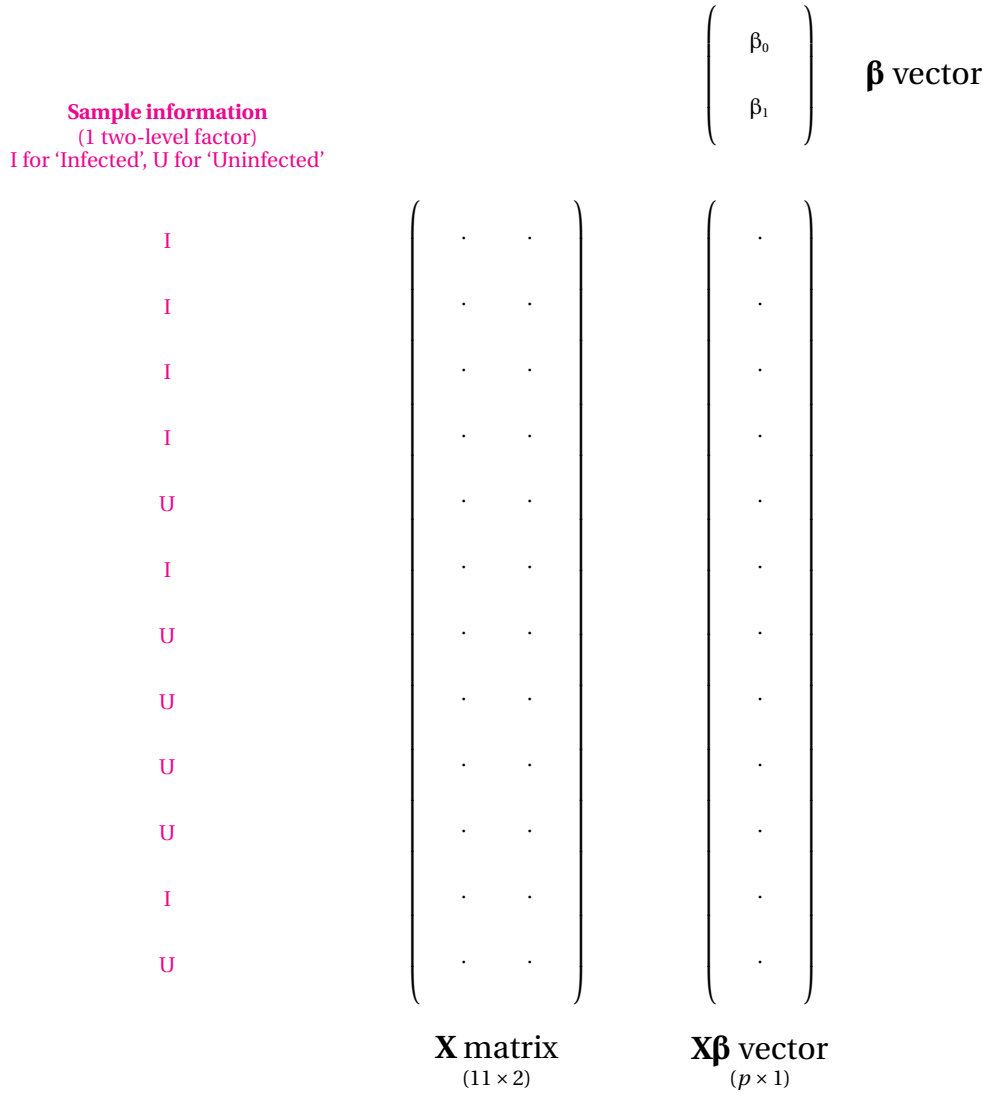
Case 2: 1 two-level factor with intercept

Modelling 2:

- Mean expression level of gene 'G' is a function of Status: Uninfected and infected.
- 2 levels = 2 parameters

Parameters: $\boldsymbol{\beta} = [\beta_0, \beta_1]^T$, where

- $\beta_0 = \mu_{\text{U}}$ is the intercept and corresponds to the mean expression level for the reference group: condition 'Uninfected'.
- $\beta_1 = \mu_{\text{I}} - \mu_{\text{U}}$ is the difference in mean expression level between conditions 'Infected' and 'Uninfected'



Design matrices for models with a two-level factor: R Code

Open the R Markdown Document 'StatsRNAseq_Couturier.Rmd' and go to Section 'Contrast matrices / One 2-level factor'

```
> dds <- DESeqDataSetFromMatrix(cnts, DataFrame(cond), ~ cond)
```

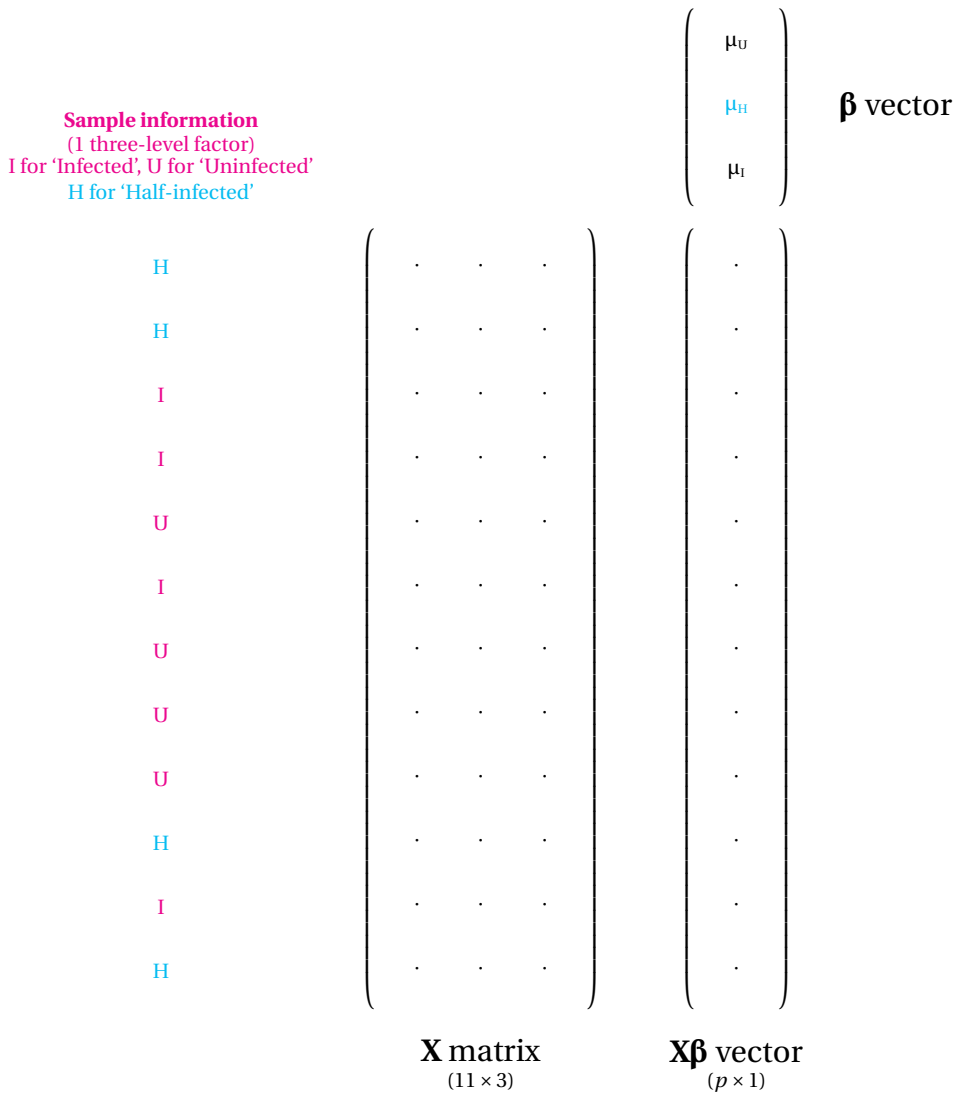
Case 3: 1 three-level factor without intercept

Modelling 1:

- Mean expression level of gene 'G' is a function of Status: uninfected, half-infected and infected.
- 3 levels = 3 parameters

Parameters: $\boldsymbol{\beta} = [\mu_{\mathrm{U}}, \mu_{\mathrm{H}}, \mu_{\mathrm{I}}]^T$, where

- μ_{U} denoted the mean expression level for condition 'Uninfected'
- μ_{H} denoted the mean expression level for condition 'Half-infected'
- μ_{I} denoted the mean expression level for condition 'Infected'



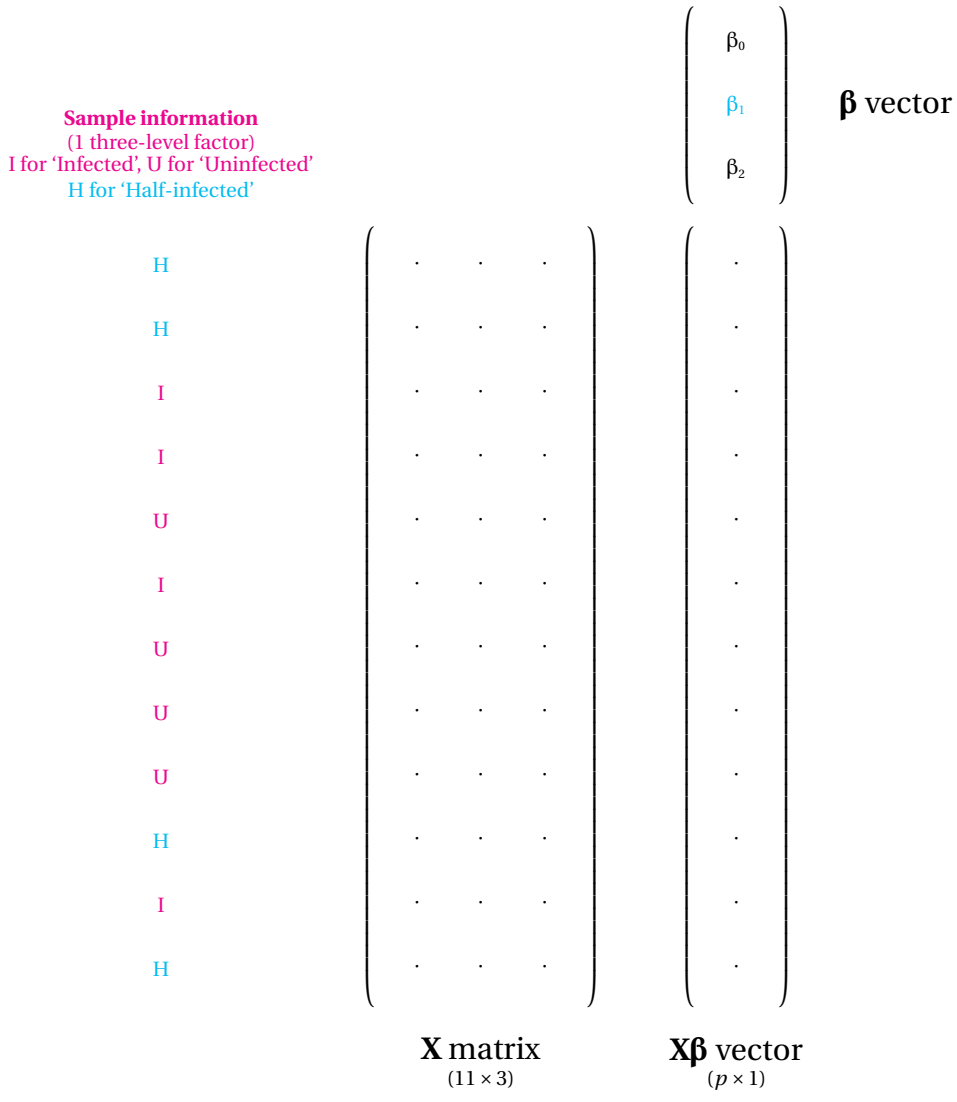
Case 4: 1 three-level factor with intercept

Modelling 2:

- Mean expression level of gene 'G' is a function of Status: uninfected, half-infected and infected.
- 3 levels = 3 parameters

Parameters: $\boldsymbol{\beta} = [\beta_0, \beta_1, \beta_2]^T$, where

- $\beta_0 = \mu_U$ is the intercept and corresponds to the mean expression level for the reference group: condition 'Uninfected'.
- $\beta_1 = \mu_H - \mu_U$ is the difference in mean expression level between conditions 'Half-infected' and 'Uninfected'
- $\beta_2 = \mu_I - \mu_U$ is the difference in mean expression level between conditions 'Infected' and 'Uninfected'



Design matrices for models with a three-level factor: R Code

Open the R Markdown Document 'StatsRNAseq_Couturier.Rmd' and go to Section 'Contrast matrices / One 3-level factor'

```
> dds <- DESeqDataSetFromMatrix(cnts, DataFrame(cond), ~ cond)
```

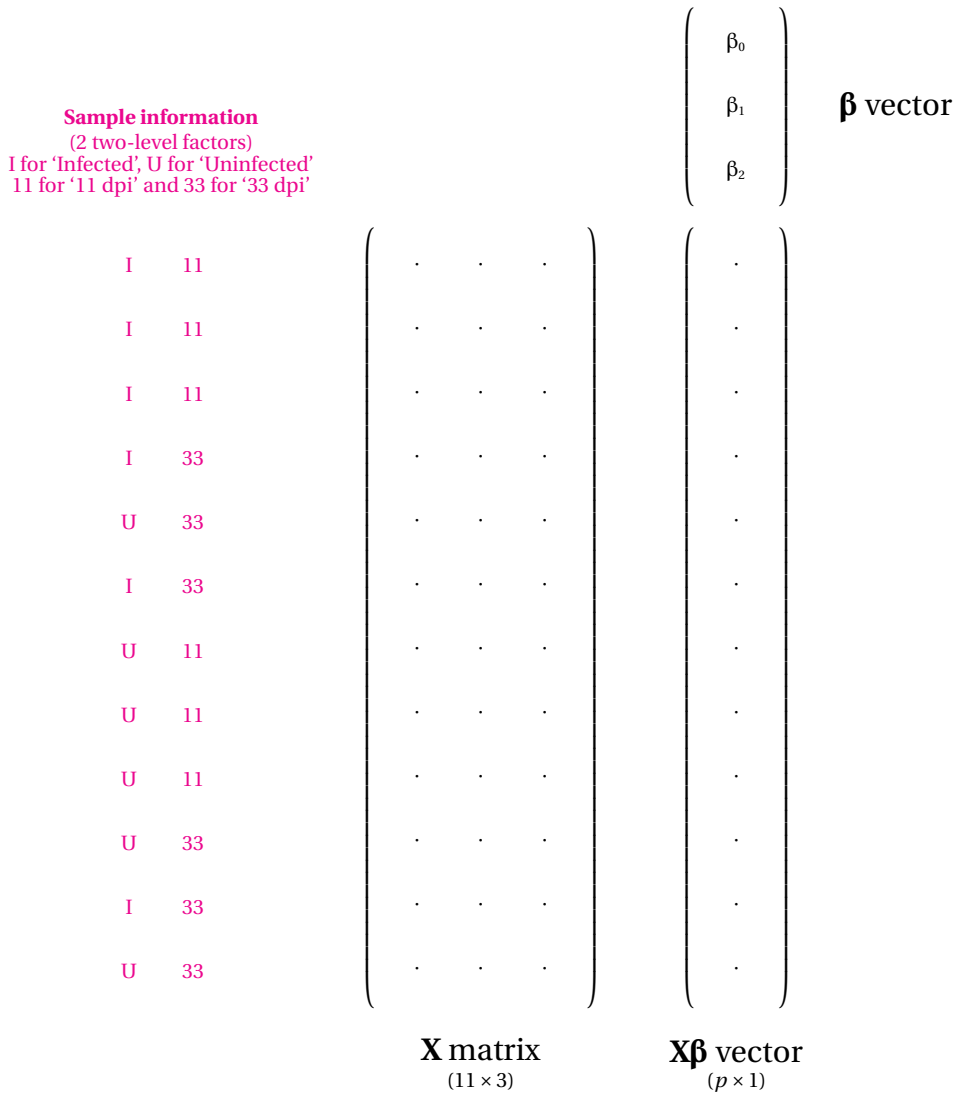
Case 5: 2 two-level factors without interaction

Modelling 1:

- Mean expression level of gene 'G' is a function of Status (Uninfected and infected) and Time (11 and 33 dpi).
- 2 (Status levels) $\times$ 2 (Time levels) $=$ 3 parameters without interaction

Parameters: $\boldsymbol{\beta} = [\beta_0, \beta_1, \beta_2]^T$, where

- $\beta_0 = \mu_{U,11}$ denoted the mean expression level for the reference group: condition 'Uninfected' at 'Time 11'
- β_1 denoted the sift in mean due to condition 'Infected'
- β_2 denoted the sift in mean due to condition 'Time 33'



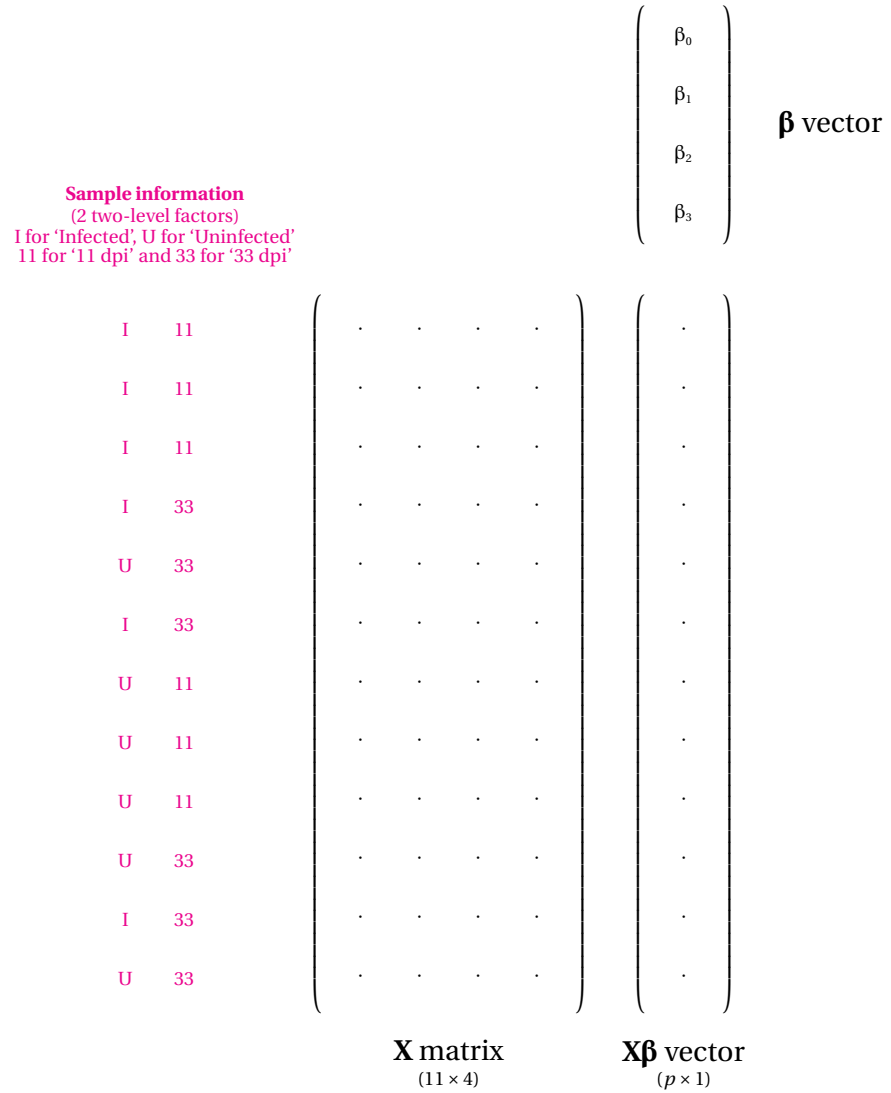
Case 5: 2 two-level factors with interaction

Modelling 1:

- Mean expression level of gene 'G' is a function of Status (Uninfected and infected) and Time (11 and 33 dpi).
- 2 (Status levels) $\times$ 2 (Time levels) $=$ 4 parameters with interaction

Parameters: $\boldsymbol{\beta} = [\beta_0, \beta_1, \beta_2, \beta_3]^T$, where

- $\beta_0 = \mu_{U,11}$ denoted the mean expression level for the reference group: condition 'Uninfected' at 'Time 11'
- β_1 denoted the sift in mean due to condition 'Infected'
- β_2 denoted the sift in mean due to condition 'Time 33'
- β_3 denoted the sift in mean due to conditions 'Infected' & 'Time 33' jointly given the main effects of 'Status' and 'Time'



Design matrices for models with two two-level factors: R Code

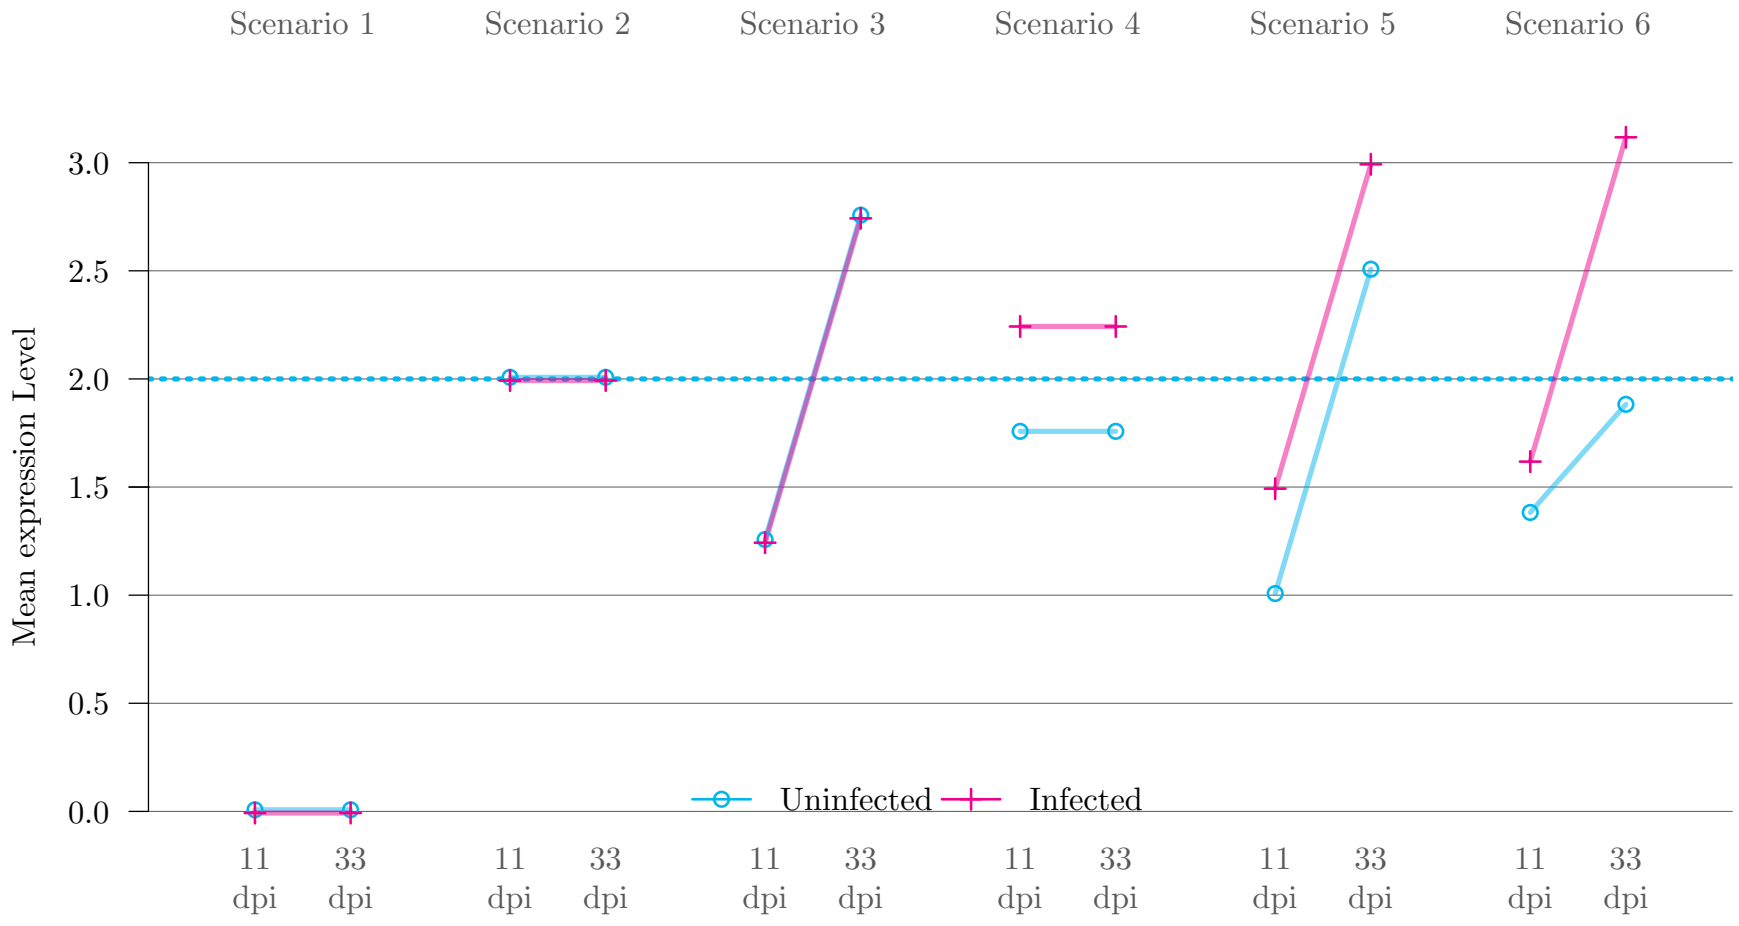
Open the R Markdown Document 'StatsRNAseq_Couturier.Rmd' and go to Section 'Contrast matrices / Two 2-level factors'

```
> dds <- DESeqDataSetFromMatrix(cnts, DataFrame(cond), ~ cond)
```

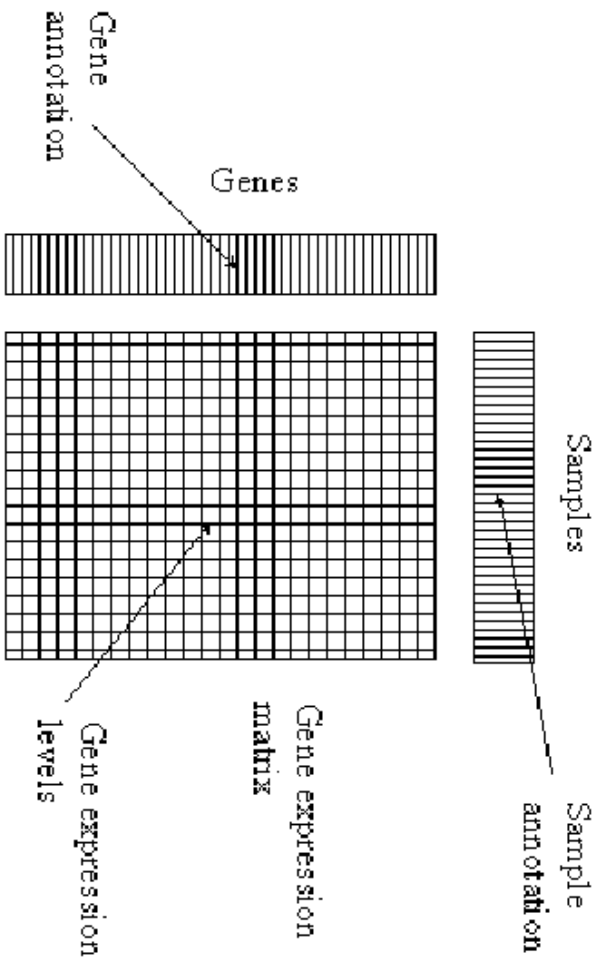
Models with 2 factors: possible scenarios

2 factors:

- Status (2 levels): Uninfected and infected
- Time (2 levels): 11 and 33 dpi



Negative binomial regression: Model



$$\mathbf{y} \sim \mathrm{NB}(\boldsymbol{\mu}, \phi)$$

$$\mathrm{E}[\mathbf{y}] = \boldsymbol{\mu} = \mathbf{s}\ 2^{\mathbf{X}\boldsymbol{\beta}}$$

where

- $\mathbf{y}$ denotes the $(n \times 1)$ **count** vector of expression intensities of a given gene,
- $\mathbf{X}$ denotes the $(n \times p)$ design/predictor matrix,
- $\boldsymbol{\beta}$ denotes the $(p \times 1)$ parameter vector,
- ϕ denotes the dispersion parameter,
- $\mathbf{s}$ denotes the scaling factor vector (library size),
- $\mathrm{E}[\mathbf{y}] = \boldsymbol{\mu}$ denotes the expectation of $\mathbf{y}$

Negative binomial regression:
Probability mass function

$$\mathbf{y} \sim \mathsf{NB}(\boldsymbol{\mu}, \phi)$$

$$f(\mathbf{y}|\boldsymbol{\mu}, \phi) = \frac{\Gamma(\mathbf{y} + \frac{1}{\phi})}{\Gamma(\frac{1}{\phi})\Gamma(\mathbf{y}+1)} \left(\frac{\phi\boldsymbol{\mu}}{1+\phi\boldsymbol{\mu}}\right)^{\mathbf{y}} \left(\frac{1}{1+\phi\boldsymbol{\mu}}\right)^{\frac{1}{\phi}}$$

with expectation and variance given by

- $\mathsf{E}[\mathbf{y}] = \boldsymbol{\mu} = \mathbf{s}\ 2^{\mathbf{x}\boldsymbol{\beta}}$
- $\mathsf{Var}[\mathbf{y}] = \boldsymbol{\mu}\left(1 + \frac{\boldsymbol{\mu}}{\phi}\right)$

Negative binomial regression: Log2 FC

```
log2 fold change (MLE): cond 2 vs 1
Wald test p-value: cond 2 vs 1
DataFrame with 1000 rows and 6 columns
      baseMean log2FoldChange     lfcSE       stat    pvalue      padj
     <numeric>      <numeric> <numeric>  <numeric> <numeric> <numeric>
1      97.3140      -0.682067  0.344525 -1.979730 0.0477339  0.745842
2     109.9860      -0.228819  0.450720 -0.507676 0.6116808  0.944354
...        ...            ...       ...       ...       ...       ...
999    89.2920       0.7554725  0.306192  2.467314 0.0136131  0.614613
1000  103.5569      -0.0728875  0.348655 -0.209053 0.8344065  0.978382
```

- $E[\mathbf{y}|\text{`cond } 1'] = 2^{\widehat{\beta}_1}$
- $E[\mathbf{y}|\text{`cond } 2'] = 2^{\widehat{\beta}_1+\widehat{\beta}_2} = 2^{\widehat{\beta}_1}2^{\widehat{\beta}_2}$
  - If not DE, $\beta_2 = 0$ so that $E[\mathbf{y}|\text{`cond } 2'] = 2^{\widehat{\beta}_1}2^0 = 2^{\widehat{\beta}_1}$,
  - If DE, $\beta_2 \neq 0$ so that $E[\mathbf{y}|\text{`cond } 2'] = 2^{\widehat{\beta}_1}2^{\widehat{\beta}_2}$
    Interpretation: *Multiplicative change in observed gene expression level of* $2^{\widehat{\beta}_2} = 2^{-0.682067} = 0.6232717$ *compared to the condition 1*

Negative binomial regression: Significance

```
log2 fold change (MLE): cond 2 vs 1
Wald test p-value: cond 2 vs 1
DataFrame with 1000 rows and 6 columns
      baseMean log2FoldChange     lfcSE       stat    pvalue      padj
     <numeric>      <numeric> <numeric>  <numeric> <numeric> <numeric>
1      97.3140      -0.682067  0.344525 -1.979730 0.0477339  0.745842
2     109.9860      -0.228819  0.450720 -0.507676 0.6116808  0.944354
...        ...            ...       ...       ...       ...       ...
999    89.2920       0.7554725  0.306192  2.467314 0.0136131  0.614613
1000  103.5569      -0.0728875  0.348655 -0.209053 0.8344065  0.978382
```

Wald Z-test to assess if a Log2 FC is significantly different from 0:

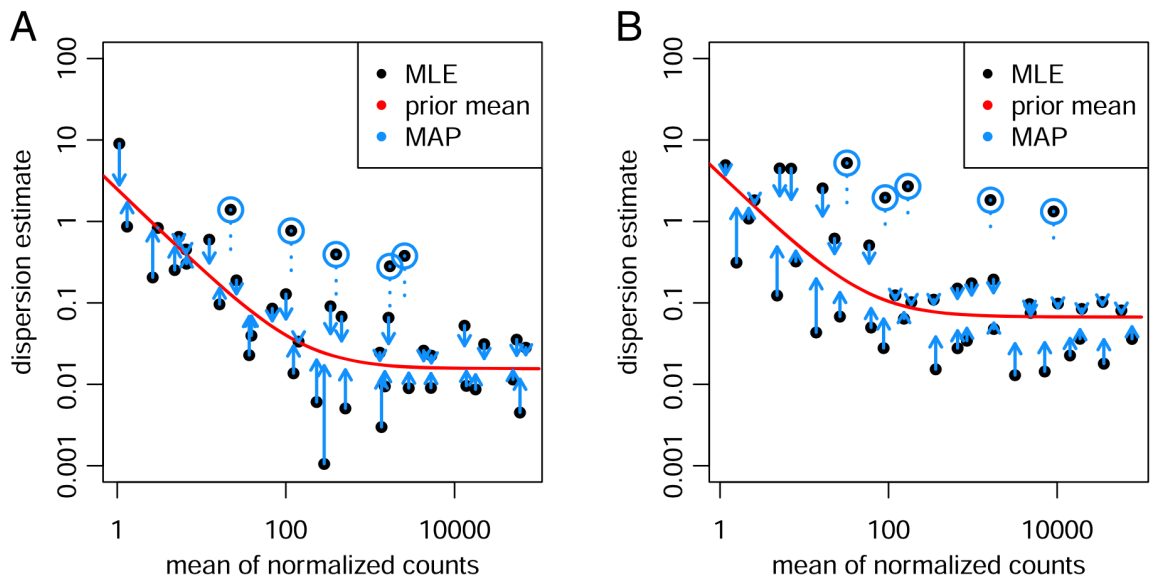
- **H0:** $\beta_2 = 0$ versus **H1:** $\beta_2 \neq 0$
- Z-statistic $= \frac{\widehat{\beta}_2}{\widehat{\sigma}_{\widehat{\beta}_2}} = \frac{-0.682067}{0.344525} = -1.979730$
- P-value with $Z \sim N(0,1)$ under **H0** is given by

```
> 2*(1-pnorm(abs(-1.979730)))

[1] 0.04773388
```

Negative binomial regression: Assumed Distribution

- The **assumed distribution of counts per condition for a given gene** depends on
  - $\widehat{\boldsymbol{\beta}}$, the estimate of the parameter vector,
  - $\widehat{\phi}$, the estimate of the dispersion parameter for that gene.
- There are **3 ways to estimate ϕ in DESeq2**:
  - gene-wise dispersion estimates via ML (black dots) [not efficient],
  - smooth curve (red line) [strong assumption],
  - Bayesian combination of both [mid-way optimal solution].

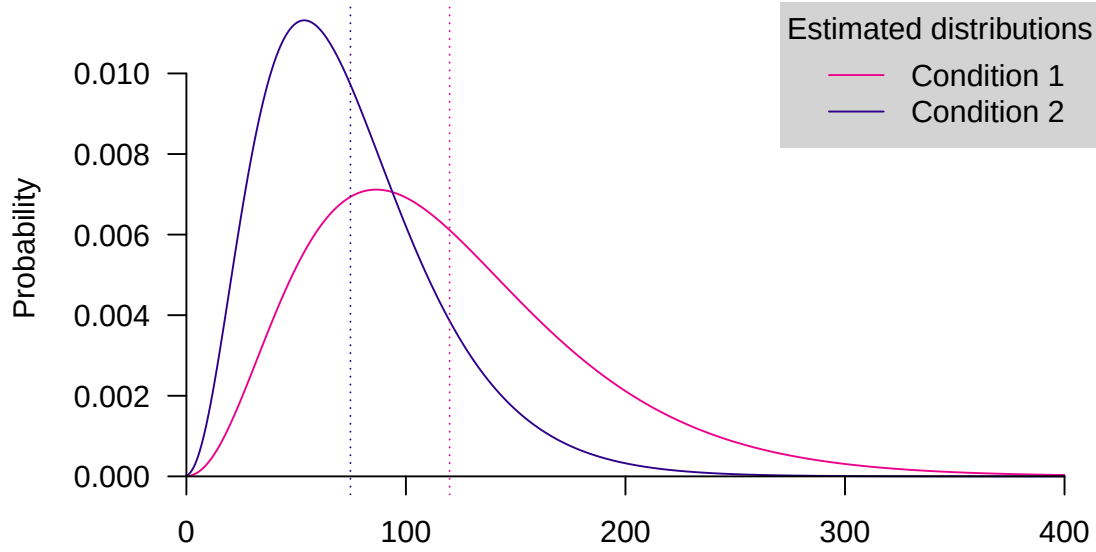


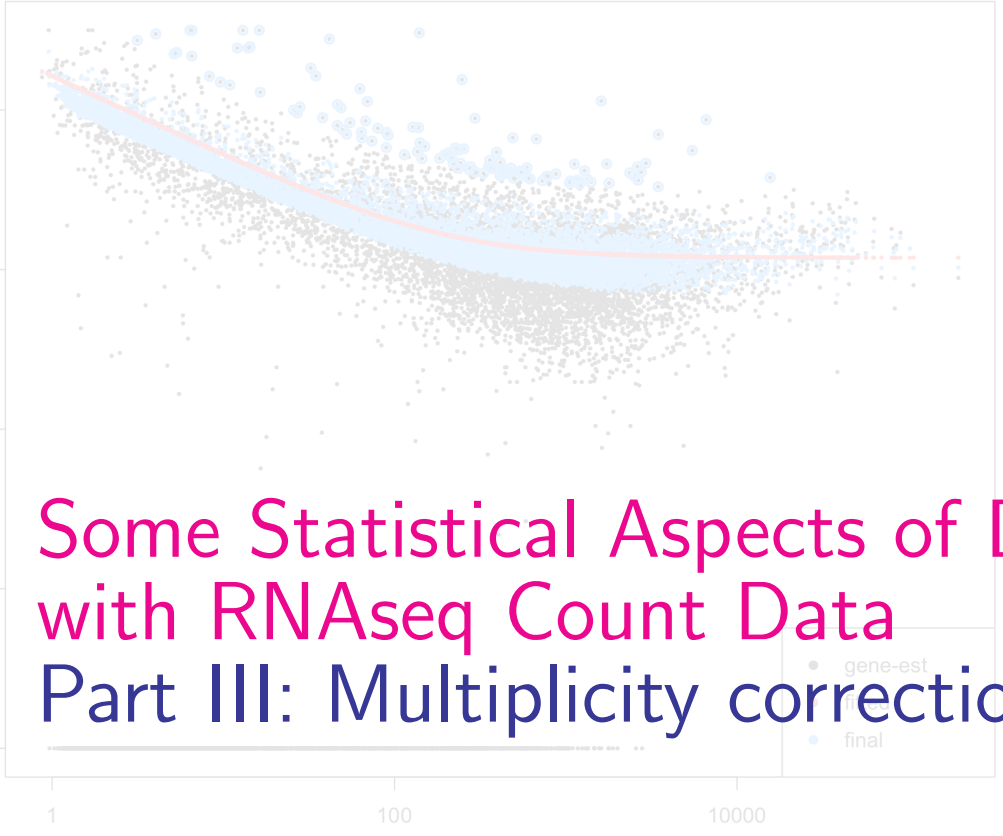
(Love et al (2015))

Negative binomial regression: Assumed Distribution

```
-> mcols(dds)[,c("Intercept","cond_2_vs_1","dispGeneEst","dispFit","dispersion")]
DataFrame with 1000 rows and 5 columns
     Intercept cond_2_vs_1 dispGeneEst   dispFit dispersion
     <numeric>   <numeric>   <numeric> <numeric>  <numeric>
1      6.90565   -0.682067    0.294082  0.234624   0.274708
2      6.89102   -0.228819    0.479231  0.230525   0.479231
...        ...         ...         ...       ...        ...
999    6.05380   0.7554725    0.206644  0.229562   0.213730
1000   6.73029  -0.0728875    0.304930  0.235483   0.282745
```

- For gene 1 and condition 1, we have
  $\mathbf{y} \sim \text{NB}(\widehat{\boldsymbol{\mu}} = 2^{6.90565} = 119.8969, \widehat{\phi} = 0.274708)$
- For gene 1 and condition 2, we have
  $\mathbf{y} \sim \text{NB}(\widehat{\boldsymbol{\mu}} = 2^{6.90565} 2^{-0.682067} = 74.72831, \widehat{\phi} = 0.274708)$





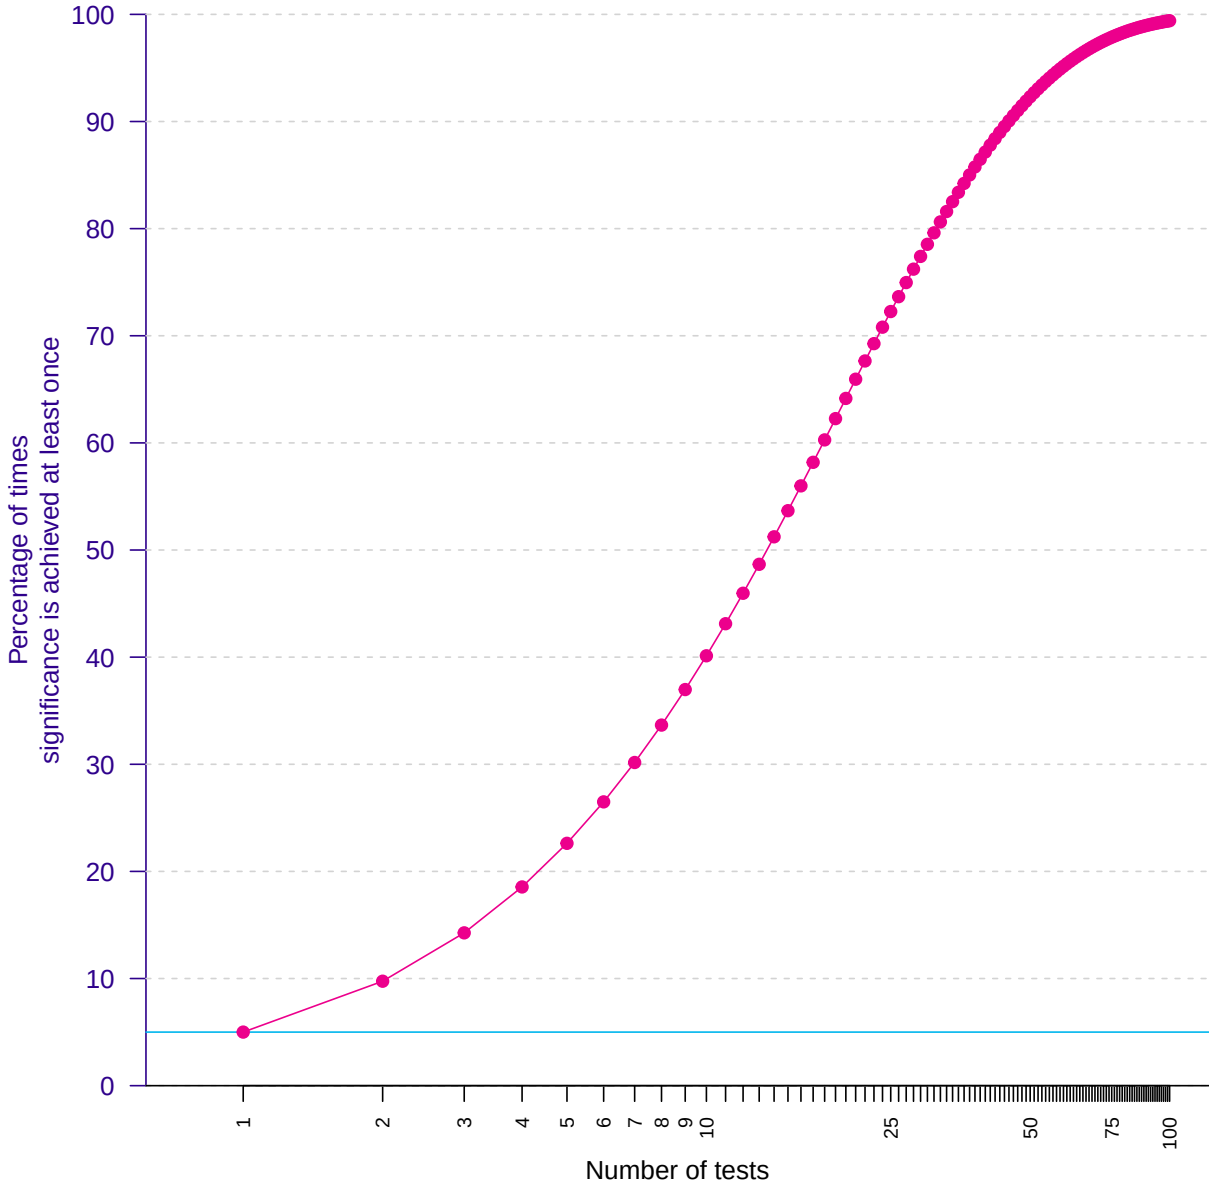
Some Statistical Aspects of DE Analysis with RNAseq Count Data

Part III: Multiplicity correction

dominique-laurent.couturier@cruk.cam.ac.uk [Bioinformatics core]

(Source: G. Marot, INRIA)

Multiplicity correction: Familywise error rate



Multiplicity correction

The Family Wise Error Rate (FWER)

Definition

Probability of having at least one Type I error (false positive), of declaring DE at least one non DE gene.

$$FWER = \mathbb{P}(FP \leq 1)$$

The Bonferroni procedure

Either each test is realized at $\alpha = \alpha^*/G$ level
or use of adjusted pvalue $pBonf_i = min(1, p_i * G)$ and FWER $\leq \alpha^*$.
For $G = 2000$, $\leq \alpha^* = 0.05$, $\alpha = 2.510^{-5}$.

Easy but conservative and not powerful.

Multiplicity correction

The False Discovery Rate (FDR)

Idea : Do not control the error rate but the proportion of error
$\Rightarrow$ less conservative than control of the FWER.

Definition

The false discovery rate of [Benjamini and Hochberg, 1995] is the expected proportion of Type I errors among the rejected hypotheses

$$\text{FDR} = \mathbb{E}(FP/P) \text{ if } P > 0 \text{ and } 0 \text{ if } P = 0$$

Prop

$$\text{FDR} \leq \text{FWER}$$

Multiplicity correction

```
> set.seed(777)

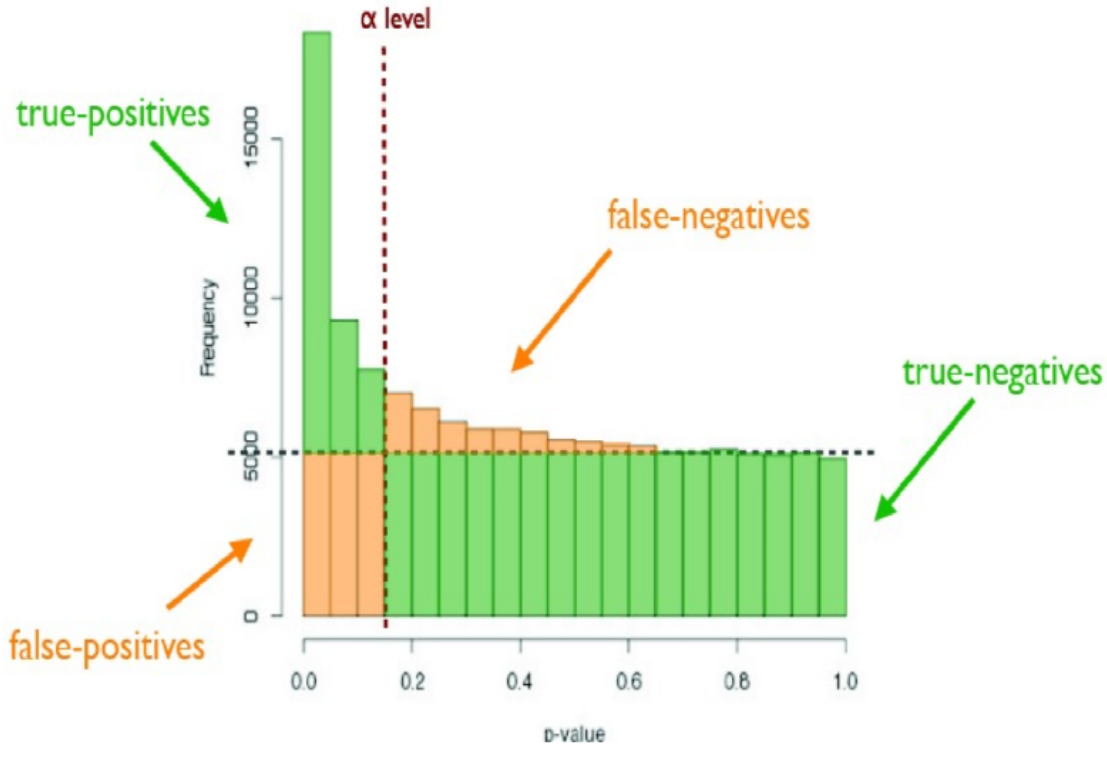
Multiplicity correction

Standard assumption for p-value distribution

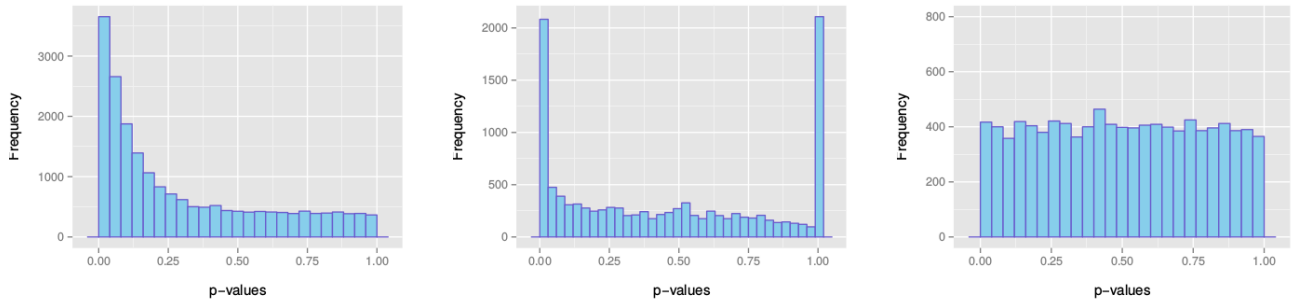


Source : M. Guedj, Pharnext

Multiplicity correction

p-values histograms for diagnosis

Examples of expected overall distribution



(a) : the most desirable shape

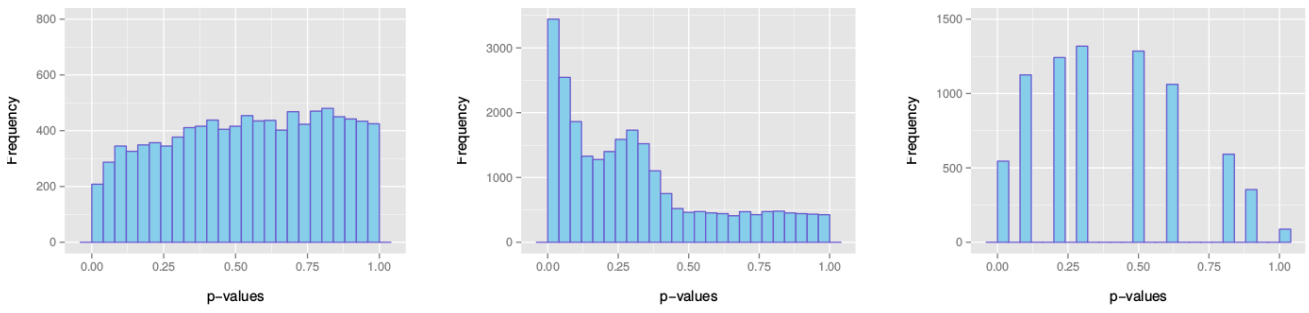
(b) : very low counts genes usually have large p-values

(c) : do not expect positive tests after correction

Multiplicity correction

p-values histograms for diagnosis

Examples of not expected overall distribution



(a) : indicates a batch effect (confounding hidden variables)

(b) : the test statistics may be inappropriate (due to strong correlation structure for instance)

(c) : discrete distribution of p-values : unexpected

CONCLUSION

```
> set.seed(777)
> cnts <- matrix(rnbinom(n=20000, mu=100, size=1/.25), ncol=20)
> cond <- factor(rep(1:2, each=10))

> dds <- DESeqDataSetFromMatrix(cnts, DataFrame(cond), ~ cond)
> dds <- DESeq(dds)
> results(dds)
```

```
